Facies, Fabrics and Organic Geochemistry of the A-1 Carbonate in Michigan

William B. Harrison, III
Michigan Geological Survey
Western Michigan University
A-1 Carbonate Production in Michigan

- Historic production is a minor component of Michigan’s overall production
- Three different geologic settings have historically produced oil or natural gas
  - Within the Silurian Niagaran Pinnacle Reef Trend on top or on flanks of reefs – Selected reefs in Otsego, Manistee, Alpena, St. Clair and Macomb Counties
  - Fractured, partially-dolomitized A-1 and A-2 Carbonate in western Michigan areas of salt withdrawal in the A-1 and A-2 Salt Fracturing and structural closure
  - Central basin fractured and partially dolomitized, not related to salt withdrawal, structural closure uncertain
Wells with A-1 Carbonate tops

Central basin fractured and partially dolomitized

Silurian Niagaran Pinnacle Reef Trend on top or on flanks of reefs

- Chester 06-30N-02W - 1,403,991 BBLs Oil and 1,431,320 MCF Gas
- Cottrellville - 206,574 BBLs Oil and 3,186,606 MCF Gas
- Bear Lake 09 - 23N - 15W - 128,563 BBLs Oil and 14,781 MCF Gas
- Charlton 28-31N-01W - 111,901 BBLs Oil and 3,756,312 MCF Gas
- Chester 05-30N-02W - 99,482 BBLs Oil and 7,725 MCF Gas
Fractured, partially-dolomitized A-1 and A-2 Carbonate in Western Michigan areas of salt withdrawal

- Dorr - 386,025 BBLs Oil and 1,729,764 MCF Gas
- Wayland - 186,499 BBLs Oil and no Gas
- Diamond Springs - 112,176 BBLs Oil and no Gas
- Caledonia - 51,435 BBLs Oil and no Gas
- Hopkins West - 43,061 BBLs Oil and no Gas
- Hilliards - 23,975 BBLs Oil and 2,458,231 MCF Gas
- Salem - 2,973 BBLs Oil and 11,337,204 MCF Gas
- Overisel – no Oil and 14,937,949 MCF Gas
- Fillmore – no Oil and 5,972,038 MCF Gas
Central basin fractured and partially dolomitized

- Au Gres - 159,262 BBLs Oil and 1,511,379 MCF Gas
- Akron - 11,709 BBLs Oil and 56,763 MCF Gas

- Rosetta-Christensen #1-21P, (P#60614) Ionia Co., 21-6N-6W (vertical pilot hole)
- Rosetta-Christensen #1-21HD1, (P#60615) Ionia Co., 21-6N-6W
Top of A-1 Carbonate Structure (subsea depths)

- Slightly oval, deep central structural basin
- Maximum subsea depth around -8000 feet or slightly over 9000 feet drilled depth
- Subsea depths in front of reef trend from -3500 to -5500 feet
A-1 Carbonate Isopach

- Relatively uniform thickness in basin center from 50 to 75 feet thick
- Encased in two thick salts several hundred feet thick each
- Thickness increases in and around the Pinnacle Reef Trends to around 100 to 150 feet thick
Lithologic Properties of the A-1 Carbonate

- Generally laminated to massive micritic limestone or dolomite. Laminae alternate with organic-rich and carbonate rich layers, often at millimeter scale. Occasional anhydrite laminae or small nodules also interbedded.
- Sparse macrofossil content due to restricted environment of deposition.
- Burrowing very limited or absent.
- Fractures, vugs and intercrystalline pores often contain clear halite.

Core and Analytical Data Available at MGRRE, Western Michigan University

- Cores from 104 wells that are located in all three of the primary geologic settings with historical production
- Drill cuttings from hundreds of additional wells
- Selected thin section of core samples and some drill cuttings
- Geochemical data for selected wells
  - TOC
  - Rock Eval
  - Thermal Maturity Analyses
Cores with Geochemical Data
Geochemical Data from Cores

- Rock Eval data for Tmax is somewhat questionable due to low S2 values
- TOC Values range from 0.1 to 3.5, with most samples from 0.3 to 0.8 Wt%
Summary

- A-1 Carbonate historic production has occurred in three separate geologic settings
  - Within the Silurian Niagaran Pinnacle Reef Trend on top or on flanks of reefs – Selected reefs in Otsego, Manistee, Alpena, St. Clair and Macomb Counties
  - Fractured, partially-dolomitized A-1 and A-2 Carbonate in western Michigan areas of salt withdrawal in the A-1 and A-2 Salt Fracturing and structural closure
  - Central basin fractured and partially dolomitized, not related to salt withdrawal, structural closure uncertain
- Facies are restricted, laminated with interlayered organic and carbonate and more carbonate-rich near the Pinnacle reef trends
Summary

- Formation is thinnest and deepest in basin center and thickens around margin in pinnacle reef trend
- TOC is low ranging from 0.1 to 3.5 Wt.%, mostly around 0.5 Wt%
- Tmax from Rock Eval analysis shows some increasing trend with increasing depth
- Porosity seems to be limited and isolated vuggy or intercrystalline (in dolomite), but fractures and secondary dissolution may enhance porosity and permeability
